

Section Eleven

Packages and Imports

Complete the Following Tasks

Task 1

Create a Class. Import that class into a main.py file to be used. This is an example of creating a local module and loading the resource for use in your main program

Task 2

Use pip3 to install the requests package. Make sure that you can import and reference the library. Why do we use pip3 and not pip?

Task 3

Create a person sub directory in your main directory. Create a Person class with first name and last attribute. In another file, create an Employee class with a salary and position attribute. Name each file respective to their class, for example, the Person class will be in a file title Person.py. The Employee class should inherit from the the Person class. Import and use the Employee class into your main.py file. Is this a package or module?
